

Enset Product Market Chain Analysis: The Case of Wonchi District, South West Shoa Zone, Oromia National Regional State, Ethiopia

Sheleme Refera¹, Abule Mehare², Mohammed Aman³

Abstract

In Ethiopia, enset is one of the indigenous root crops widely cultivated in the south and southwestern parts. Particularly in Wonchi district it is a major source of food and cash income for majority of smallholder farmers. This study aimed to identify enset product market actors and their roles; to identify enset product market channels; and to analyze enset product marketing margin in Wonchi District. Both primary and secondary data were used for the study. Primary data were collected from randomly selected 184 sample enset producers through two stage sampling technique and from 33 kocho traders. The data were analyzed using descriptive methods. The result indicated that producers, wholesalers, retailers, village collectors and consumers were the enset product (kocho) market chain actors. The benefit share of producers ranges from 65.01% (channel III and IV) to 100% (channel I). Responsible bodies should pay an attention in optimizing the benefit share and minimizing unbalanced share of benefit among the market actors and rising experience producers through experience sharing on the enset production.

Keywords: Enset, Market Actors, Market Channel, Marketing Margin, Wonchi District.

1. Introduction

In Ethiopia, root and tuber crops are the second largest crops, after cereal crops in terms of magnitude of production (CSA, 2017). Those crops contribute a major share in traditional food system of many people. They play a vital role in food security especially in south and southwestern part of Ethiopia. *Enset*, *anchote*, potato, onion, carrot, yams, taro and cassava are the major root and tube crops grown in the country (Yeshitila and Temesgen, 2016).

Enset (*Enset ventricosum*) is one of the indigenous root crops widely cultivated in the south and southwestern parts of Ethiopia. *Enset* domestication started in Ethiopian highlands between 5,000 and 10,000 years ago (Brandt *et al.*, 1997). It looks like a large, thick single stemmed banana like plant. Usually, it is larger than banana and 6-12 meters tall. Its leaves are 5-7 meters tall and 1 meter in diameter and are more erect than a banana plant. Its cultivation can be restricted to altitudes between 1600 and 3000 masl with an average annual rainfall of 1100 to 1500 millimeter and is chiefly propagated vegetative (Belachew *et al.*, 2016).

According to CSA (2013) the total area under *enset* crop in Ethiopia was estimated to 312.17 thousand hectares, whereas the total area under this crop in Southern Nations Nationalities and Peoples Regional State is 217 thousand, Oromia 94 thousand and Gambella region 0.382 thousand hectares. During Meher season from Ethiopian private peasant, total of 127.3 million *enset* crops were harvested and produced 34.8 million quintals of *kocho*, 1.1 million quintals of *bulla* and 29.4 million quintals of *amicho*.¹ In the same period, 45.7 million *enset* plants were harvested and produced 11.9 million quintals of *kocho*, 680.6 thousand quintals of *bulla* and 10.1 million quintals of *amicho* in Oromia region (CSA, 2017). From Oromia region Jimma, Borana, Guji, West Arsi, South West Shoa and West Shoa Zones are the *enset* potential Zones (CSA, 2015). The South West Shoa Zone is one of the outstanding *enset* crop accommodated area.

From 95 thousand hectares of total farming, 18.3 thousand hectares were under *enset* farming and is cultivated by 73153 households in the zone (SWSZ ANRO, 2018). The crop is produced in all districts of zone except Sodo Daci and Ilu districts. Wonchi (also pronounced as *Wonci*) district is one of the potentials and well known area by *enset* crop production, about 5428 hectares of the districts' cultivated land is covered by this crop and all kebeles in the district produce the crop.

Enset is considered as a food security crop in different parts of Ethiopia as it can withstand long periods of drought, heavy rains, and flooding, which devastate other crops (Daniel and Getaneh, 2015). It

¹ *Meher* is a main season between September and February.

is grown largely for food security reasons, if cereal crops fail and eaten in the form of *kocho* and *amicho*. Therefore, *enset* is called “The tree against hunger” in Ethiopia (Sadik *et al.*, 2016). It is a major crop where more than 20% of the people in Ethiopia depend on this crop mainly in the southern and south western parts (Alemayehu, 2017). The crop has also used as farmers’ adaptation strategy to climate change (Laila *et al.*, 2016).

Mesfin *et al.* (2018) listed *kocho*, *bulla* and *amicho* as the major food products obtained from the *enset*. From the three food products of the *enset*, *kocho* and *bulla* were supplied to different markets from production site. Due to its perishable nature, *amicho* is not delivered to markets. In this study *enset* product refers to only *kocho*. According to Abebe *et al.* (2015) the largest proportion of *kocho* were supplied to the market rather than consumption.

Enset crop is crucial in the Ethiopian context and specifically in the study district. It has a significant contribution to the livelihood of producers as income sources as well as ensuring of food security. Currently, about 19860 households of Wonchi district are engaged in the production of this crop and leading their life based on *enset* farming. The activity is mainly meant for additional income generating activity on top of other crop production like maize, *teff*, wheat and barley and livestock rearing. In fact, *enset* has been the main food and cash crop in the district (WDANRO, 2018). Specifically, in Wonchi District marketing chain analysis of *enset* product is not investigated so far.

Given the importance of *enset* crops understanding the *enset* product market chain is crucial. The specific objectives of the study are as follows:

1. To identify *enset* product market actors and their roles.
2. To identify *enset* product market channels.
3. To analyze *enset* product marketing margin in Wonchi District.

2. Research Methodology

2.1: Description of the Study Area

Wonchi district is located in Oromia regional state of South West Shewa Zone, Ethiopia. It is one of the eleven districts in southwest Shewa zone and about 9 kilometers and 123 kilometers from Waliso town and Addis Ababa, respectively. The districts approximately found between 1600 and 3576 meter above sea level. Wonchi district is bordered on the southwest by Goro, on the west by Ameya, on the north by Ambo, and on the east by Waliso districts. The district has 23 rural kebeles (WDANRO, 2018).

The district has two agro-ecologies; highlands (40%) and midlands (60%). The mixed farming system of both crops and livestock are common economic activity in the district. The important crops

grown in the district are maize, *teff*, wheat, barley, *enset*, and onion. According to WDTMDO (2018) in 2017/2018 production year 835352 quintals of cereal grain, 8078 quintals of pulse grain, 281723 quintals of horticultural crops, 31764 of live-animals, 5253 tones of hide and skin were supplied to the market. Moreover, 39936 quintals of *enset* products (*kocho and bulla*) were supplied to the market. In general, Wonchi district is the major producer of *enset* from southwest Shewa zone and *enset* production is considerable sources of cash in the district (WDANRO, 2018).

2.2: Data Types, Sources and Methods of Data Collection

This study used household survey data collected from Wonchi District. In order to generate sufficient information, both quantitative and qualitative data from primary and secondary data sources were used. Primary data were collected from randomly selected *enset* producers and *kocho* traders. To collect primary data semi- structured questionnaire were prepared and pre-tested on sampled *kebeles* to evaluate the appropriateness of the design, clarity and amended based on feedback. The data was collected using two type of questionnaires; one for producers and the other for *kocho* traders. In addition, checklist was used to generate data through focus group discussion and key informant interview.

2.3: Sampling Techniques and Sample Size

Two stages random sampling method was used to select the sample household heads. In the first stage out of 23 *kebeles*, five *kebeles* were selected randomly from the district. In second stage, from the list of *enset* producer households in the sampled *kebeles*, 184 households were selected randomly. The total number of households taken from each *kebeles* was based on, Pandey and Verma (2008) proportional sample allocation formula and given by equation below:

$$n_i = \frac{nN_i}{N} \quad \dots\dots(1)$$

Where: n_i = Sampled households from i^{th} *kebele*

n = Sample size

N_i = The total households in i^{th} *kebele*

N = Total households in selected *kebele* (sum total of households in five *kebele*)

Table 1. Sample distribution of *enset* producer households in selected kebeles

No	Kebeles	Total households in the kebele	Sampled households
1	Haro Wonchi	1068	46
2	Weldo talfem	1010	44
3	Worabu masse	516	25
4	Haro basaka	646	30
5	Sonkole kake	904	39
Total		4144	184

Source: WDANRO, 2018 and own computation result

Sampling of traders remains difficult due to lack of complete data on the number of *kocho* traders list in the district as well as in the Waliso town. As a result, traders available during survey in the market were considered. Accordingly, data were collected from 33 *kocho* traders (Wholesalers, Retailers and Village collectors) from three village markets in the district where large volume of *kocho* transactions take place namely; Haro, Aroji, Warabu markets and one Central market, Waliso *kocho* barenda which is found in Waliso town respectively (Table 2).

Table 2. Distribution of *kocho* traders by market

Type of traders	<i>kocho</i> traders				
	Haro	Aroji	Worabu	Waliso	Total
Wholesalers	4	1	-	4	9
Retailers	3	2	3	-	8
Village collectors	5	6	5	-	16
Total	12	9	8	4	33

Source: own computation result (2018).

3.4. Methods of Data Analysis

To describe the demographic and farm inputs used by sampled *enset* producers and *kocho* traders in the study area the descriptive statistics were used. Marketing margin analysis was used to evaluate the margin of the *kocho* market channels in the study area. Total gross marketing margin calculation is always related to the final price paid by end consumer and is expressed as a percentage. Thus, the total gross marketing margin was computed using the equation (2) below;

$$\text{TGMM} = \frac{P_c - P_p}{P_c} \times 100 \quad \dots(2)$$

Where: TGMM = Total gross marketing margin

P_c = Consumers price

P_p = Producers price

The producers' margin or share in the consumer price (GMM_p) was calculated by equation (3);

$$GMM_p = \frac{P_c - TGMM}{P_c} \times 100 \quad \dots\dots(3)$$

$$GMM_p = 100\% - TGMM$$

Where: GMM_p = Producers share in consumer price

Precise marketing costs are frequently difficult to determine in agricultural marketing chains, for these reasons net marketing margin was not calculated.

3. Results and Discussion

3.1. Demographic and Socio-economic Characteristics of Sample *Enset* Producer Households

From total of 184 sampled *enset* producers 118 (64.13%) were participants in *kocho* market while the remaining 66 (35.87%) were non- participants during 2017/18 production year. From total sample producers 105 (57.07 %) were female headed including female spouse in male headed and the remaining 79 (42.93%) were male headed households. Among *kocho* market participants, female and male headed households constitute 70(59.32%) and 48(40.68%) respectively.

3.2. Land ownership and its utilization by sampled *enset* producer households

One of the most important factors that influence crop production is availability of land. The sources of total land operated by the sampled households during survey period was divided as owned land, rent-in and share-in farmland. The analysis of survey data show that the average total land sizes allocated for *enset* production by sampled respondents was about 0.27 hectares and owned by the sample respondents was 1.55 hectare. This average land holding size by sample respondents is lower than 1.7 hectare in Oromia and higher than 1.4 hectare per household at national level (CSA and WB, 2013).

Table 3. Land ownership and its utilization by sampled respondents

Total land and its source	N	Minimum	Maximum	Mean
Total land (ha)	184	0.750	4.125	1.700
Owned land (ha)	184	0.500	4.125	1.550
Rent in(ha)	40	0.250	1.500	0.450
Share in(ha)	15	0.250	1.000	0.530
Land utilization				
Cereal crops (ha)	180	0.250	3.000	1.030
<i>Enset</i> crops (ha)	184	0.063	0.500	0.270
Pulse crops (ha)	68	0.013	0.500	0.220
Grazing land (ha)	176	0.063	0.750	0.280
Other crops (ha)	31	0.063	0.500	0.270

Rent out (ha)	7	0.250	0.500	0.320
---------------	---	-------	-------	-------

Source: Own survey result (2018).

3.3. Demographic and Socio-economic Characteristics of *Kocho* Traders

From a total of 33 sampled traders 27.27% are wholesalers, 24.24% are retailers 48.48% are village collectors. As indicated in Table 4, out of the total sample traders, 87.87% were female and 12.13 % were male since in the study area trading *kocho* is regarded as females’ activity. Unlike trading in other activities, female in the study district are more motivated in *kocho* trading due to less competition from male counterparts. Among sampled *kocho* traders, only 27.27% of them have legal trading license and 72.73% of them do not have license. The survey result also shows that about 87.87% of traders are trading alone since they are female and 12.13% traders are trading with his wife because of checking the quality and packing the *kocho* purchased is not allowed for male.

Table 4. Distribution of traders by their sex, trading license and ways of trading

Variables		<i>Kocho</i> traders							
		Wholesalers (N=9)		Retailers (N=8)		Village Collectors (N=16)		Total sample (N=33)	
		N	%	N	%	N	%	N	%
Sex	Female	5	55.55	8	100	16	100	29	87.87
	Male	4	45.45	-	-	-	-	4	12.13
Trading license	Yes	9	100	-	-	-	-	9	27.27
	No	-	-	8	100	16	100	24	72.73
Ways of trading	Alone	5	55.55	8	100	16	100	29	87.87
	With wife	4	45.55	-	-	-	-	4	12.13

Source: Own survey result (2018)

The mean age of the sample *kocho* traders were 36 years ranging from 25 to 50 years. The mean family sizes of the traders were 4.84 families per traders with ranging 3 to 10 family sizes. Regarding educational level of traders, survey result shows that mean education level of traders was 5.09 years of formal schooling. On average sampled traders have 7.81 years of *kocho* trading experience.

The mean initial working capital of sampled *kocho* traders were 4639.39 ETB ranging from 500 to 20000 ETB and Own saving is the solely source of working capital for the sampled *kocho* traders. Currently working capital was reached on average 22175.76 ETB ranging 1800 to 100000 ETB (Table 5).

Table 5. Socio-demographic characteristics of sample traders

Variables	<i>Kocho</i> Traders			
	Wholesalers	Retailers	Village collectors	Total sample
	Mean	Mean	Mean	Mean
Age	41.50	34.13	36.00	36.00
Family size	5.25	3.75	4.93	4.84
Educational level	7.75	5.00	4.00	5.09
<i>Kocho</i> trading experience	14.00	2.38	5.62	7.81
Initial working capital	13250.00	1262.50	2750.00	4639.39
Current working capital	77500.00	3725.00	9812.50	22175.76

Source: Own survey result (2018)

3.4. *Enset* Production and Amount of *Kocho* Produced by Sample *Enset* Producer Households

In the study area growing *enset* is one of the most important crop cultivation which has been playing an important role in the livelihoods of the growers by serving as food and cash source. It also serves as feed for livestock and airing in most cases. *Enset* plantation is mainly undertaken during winter months of December, January and February, and it can be harvested throughout the years. During focus group discussion a farmer said that ‘having one *enset* crop was more than having one quintal of cereal crops and also he called *enset* is their gold crop’.

The common farm inputs used in *enset* production in study area includes: manure and compost, fertilizers, local *enset* seed variety. About 91.30% of respondents used manure and compost as organic fertilizer and only about 8.70% used both manure and compost and inorganic fertilizers. The survey result showed that about 79.89% *enset* producing farmers get sources of *enset* seeds from their own farm by planting *enset* seeds. About 13.04% of *enset* producing farmers used *enset* seeds purchased from the private owner (friends and neighbors) and the remaining 7.07% of farmers used both own farm and purchased *enset* seeds.

All sample *enset* producers were found to be used local varieties of *enset* plant. It was found that more than 10 *enset* varieties were grown in the districts for different purposes. These varieties had their local names based on their morphology difference, color and purposes of uses. From these varieties, five varieties were the most common in the study area. The most important varieties as per farmers’ ranking were: *baladeti*, *farase*, *hawegne*, *beshalga* and *urage* (FGD). The main sources of labor used for *enset* production includes family labor, hired labor and, *debo* and *wonfel*. About 57.65%, 31.35% and 11% of *kocho* market participants used family labor, hired labor and, *debo* and *wonfel* respectively. While non-participants 87.88% and 12.12% used family labor and, *debo* and *wonfel*. The use of family labor in *enset* production was common for both market participants and non-participants in the study area.

Table 6. Sources of *enset* seeds

Item	Participants		Non- participants		Total sample	
	N	%	N	%	N	%
Planting	89	75.42	58	87.87	147	79.89
Purchasing	17	14.41	7	10.61	24	13.04
Planting and purchasing	12	10.17	1	1.52	13	7.07

Source: Own survey result, 2018.

3.5. Kocho Market Chain Actors and Their Roles

Five *kocho* market actors have been identified in the *kocho* market chain in Wonchi district. These actors were producers, wholesalers, retailers, village collectors and consumers.

The producers are *enset* growing farmers in study area. They are major actor involved in both production and marketing of *kocho*. Mainly they started production from input preparation such as *enset* seed to be planted, preparing land, planting it and processing, producing, provide *kocho* surplus to the market. This actor manage the crop up to the plant get matured for harvesting. As the plant becomes matured, producers themselves process the plants into its main products as *kocho*. To produce *kocho* they harvest the matured *enset* plants from its main field, scraping the pseudo-stem and pulverizing the corm, and covering area with *enset* leaves. Then, ferment the mixture of scraped pulp of pseudo-stem and pulverized corm together in the pit which is lined with *enset* leaves. *Enset* producers in Wonchi district supply their product either to nearest *kocho* market or central *kocho* market using horse cart, pack animal, truck or sales at farm gate to traders. According to the study result, 60.03% and 39.97% sold *kocho* within village markets and outside village market (waliso *kocho* barenda) respectively.

Wholesalers are the actors of *kocho* marketing those who buy large volume and have enough capital as compared to other market actors. There are two types of wholesalers. Those are; district wholesalers and central wholesalers which found in major city of Waliso town. District wholesalers are buying *kocho* either from producers or village collectors while Waliso wholesalers mostly buy from districts wholesalers and village collectors, sell to hotel and restaurants in Waliso town and Addis Abeba. It is also to be noted that all the wholesalers have license to do wholesale in the study district.

Retailers are market actors operating with minimum capital in the channels selling to consumers. They mostly buy *kocho* from producers and small portion from the village collectors and resell directly to ultimate consumer. They perform several value addition activities such as transporting, clearing fibers from *kocho* in good manner and selling to end users.

Village collectors are the main actors in *kocho* market chain and playing important role in collecting *kocho* from producers directly at farm gate and at village *kocho* market for the purpose of reselling to wholesalers and retailers. They are not licensed traders.

Consumers are those who purchase and consume *kocho* supplied by traders and/or producers. Consumers usually buy *kocho* in small amount to meet their family need. They are the last link in the *kocho* market chain. *Kocho* market chain ended at consumers who buy the products for the ultimate consumption.

3.6. Kocho Marketing Channels

From a total of 813 quintals *kocho* supplied by sampled producers and purchased by wholesalers, retailer, village collectors and consumers was about 332 quintals (40.84%), 177 quintals (21.77%), 257 quintals (31.61 %) and 47 quintals (5.78%) respectively (Figure 1). According to survey result wholesalers and village collectors were the dominant buyers of *kocho* from producers. From view point of *kocho* market flow, out of total *kocho* sold by market participants 44.9% (365.12 quintals) were marketed to Addis abeba. Six *kocho* marketing channels were identified through which *kocho* reaches final consumer during its flows from the producer. From the total volume of *kocho* sold by sample producers the largest amount has passed through channel V (177 quintals) and channel VI (122.85 quintals) followed by channel IV (64.15 quintals) and then channel I, while the least volume of *kocho* (9.43 quintals) transaction passes through channel II.

Channel I: Producers → Consumers 5.78% (46.99 quintals)

Channel II: Producers → Village collectors → Retailers → Consumers 1.16% (9.43 quintals)

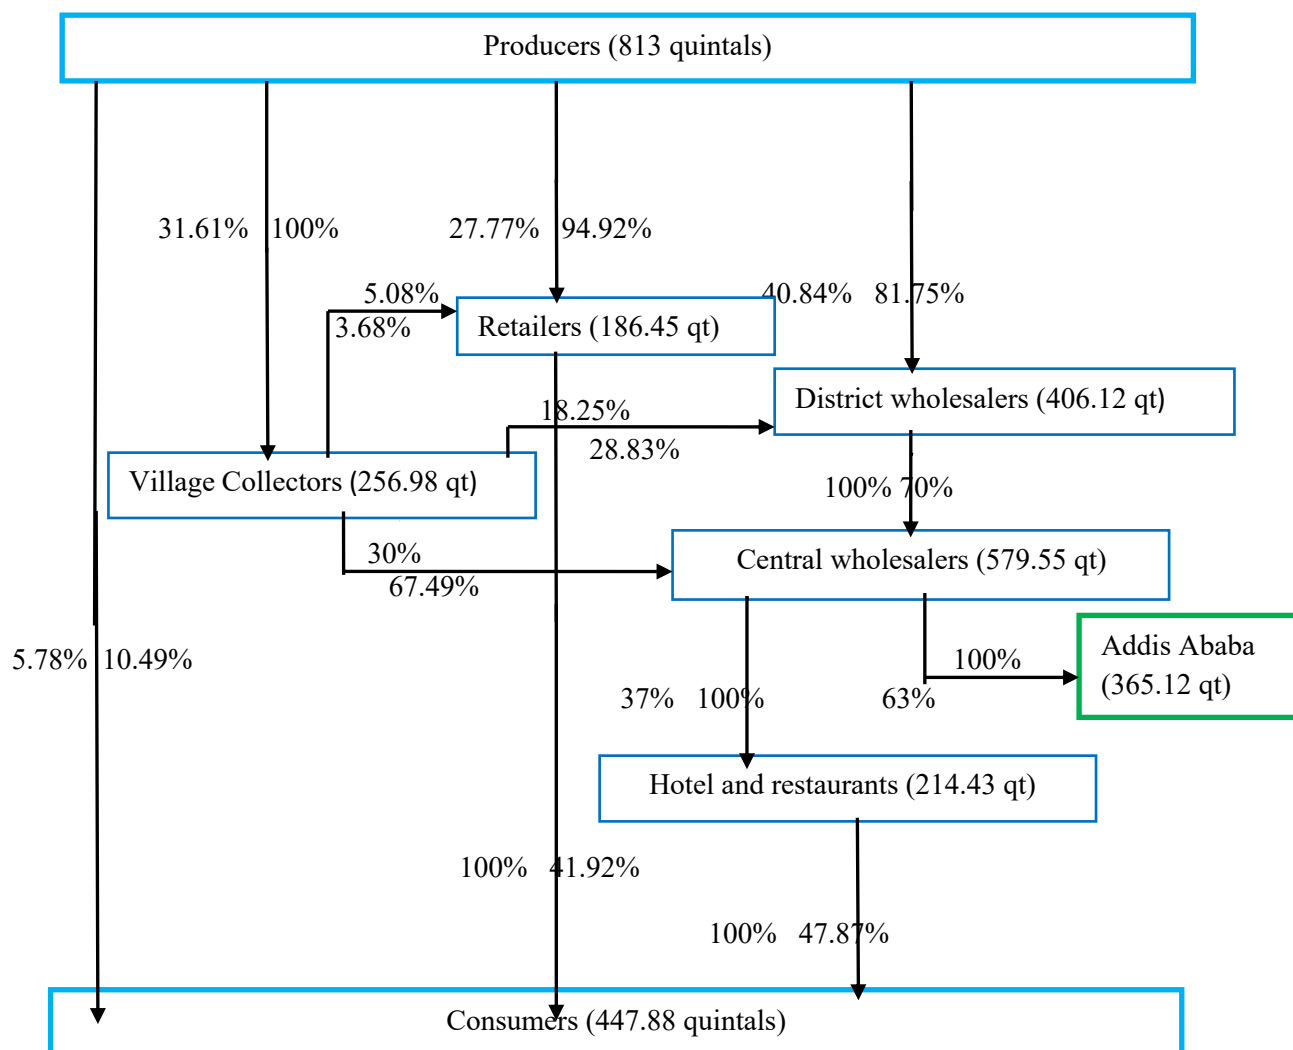

Channel III: Producers → Village collectors → District wholesalers → Central wholesalers → Hotel and restaurants → Consumers 3.37% (27.40 quintals)

Channel IV: Producers → Village collectors → Central wholesalers → Hotel and restaurants → Consumers 7.89% (64.15 quintals)

Channel V: Producers → Retailers → Consumers 21.77% (177 quintals)

Channel VI: Producers → District wholesalers → Central wholesalers → Hotel and Restaurants → Consumers 15.11% (122.85 quintals).

Figure 1. *Kocho* marketing channels in study area

Note: Percent in left or below arrow indicate percent share of supplying actors

Percent in right or above arrow indicate percent share of receiving actors

Source: Own sketch from survey result (2018).

3.7: *Kocho* Marketing Cost and Margin Analysis

Due to difficulty in obtaining data on production and marketing costs from *enset* producers, transaction cost was calculated only for traders. The average marketing costs of *kocho* for traders were calculated and presented in Table 7. *Kocho* marketing costs mainly constitutes cost of transportation, storage, storage keeper, storage lost, market information search, packing, loading and unloading and packing material. The total marketing cost per quintal incurred by *kocho* traders; village collectors, retailers, district wholesalers and central (waliso) wholesalers were 58.4, 20, 146 and 169.75 ETBs respectively.

Table 7. Kocho average marketing costs for traders (Birr/quintals)

Marketing cost	Traders			
	Village collectors	Retailers	District wholesalers	Central wholesalers
Transportation cost	15	10	28	30
Storage rent	5	-	6.25	10
Storage keeper cost	5	-	5	5
Storage lost	-	-	52.25	47.25
Cost of market information search	6.6	-	5	5
Packing cost	10	-	12.5	20
Cost packing material	6.8	-	15	22.5
Loading and unloading cost	10	10	22	30
Total cost	58.4	20	146	169.75

Source: Own survey result (2018).

As mentioned earlier marketing margin is the percentage of price paid by consumers that goes to market actors in the marketing channel can be measured by calculating gross marketing margin for actors in different marketing channels. Based on the reported prices by the different actors table 8 provide an overview of the marketing margin among different actors in different channels. As shown in Table 8, total gross marketing margin (TGMM) was the highest in channel III and IV (34.99%) and the lowest in channel V (11.55%). According to survey result producers share (GMMp) was the highest in channel I (100%) followed by channel V (88.45%) and the lowest in channel III and IV (65.01%). Gross marketing margin for traders also calculated and as indicated in table 8, Village collectors gross market margin (GMMVc) is the highest in channel IV (9.52%) while retailers (GMMr), district wholesalers (GMM_{dw}) and central wholesalers (GMMcw) traders are highest in channel V, VI and IV and it accounted 11.55%, 17.23% and 25.47% respectively.

The result also indicate that village collectors, retailers, district wholesalers and central wholesalers gain highest gross profit per quintal in channel IV (81.6 ETB), V (108.5 ETB), VI (106 ETB) and IV (202.75 ETB) respectively.

Table 8. Marketing margins (birr per quintal) of kocho market channels

Market actors	Items	Kocho marketing channels					
		I	II	III	IV	V	VI
Producers	Selling price	1080	950.71	950.71	950.71	984	1028
	GMM _p (%)	100	85.45	65.01	65.01	88.45	70.29

3.8: Production and Marketing Constraints of *Enset* Producers

Production constraints

Enset crop has been used for multipurpose as food and cash crop in the study district. But its production has some constraints. According to the data obtained from group discussion among *enset* producers some problems on this crop are lack of *enset* seed variety, *enset* disease what they call in local name *tortorsa*, *bosbosa* and drying and farmers still used cultural *enset* diseases management like applying livestock urine to diseased *enset*.

Weak support from government regarding *enset* production unlike other agricultural production is another production constraint. The other constraints were lack of *enset* processing technologies and lack of kocho storage; still they used traditional tools and local made equipments for *enset* processing without any scientific modification which is leading to loss the products, lack of knowledge on inorganic fertilizers for *enset* production, *enset* farmers mostly used farm yard manure what they call *dike* which is not sufficient for *enset* production. *Enset* takes long time for maturity period and its production is boring and its working culture gives burden on women.

Marketing constraints

The most important *kocho* marketing constraints faced by *enset* farmers in the study area during the survey period were low price and price fluctuation of *kocho*, lack of transport, limited access to *kocho* market information, far distance of the central market from producers location, poor *kocho* market policies, poor linkage with market chain actors, lack of storage facilities and low demand of *kocho*. These constraints are analyzed by ranking index. The ranking index shows that low price and price fluctuation of *kocho*, limited access to *kocho* market information, and lack of adequate transport service are ranked 1st, 2nd and 3rd respectively. Additionally, market constraints raised by traders especially district

wholesalers there were informal traders like village collectors who have no trading license to trade *kocho* is influencing the work the district wholesalers they purchase from farmers and they sell to central wholesalers by low price since they are not paying taxes.

Table 9. *Kocho* marketing constraints

Constraints	Rank count of respondents						Ranking index	Rank
	1 st	2 nd	3 rd	4 th	5 th	6 th		
Low price and its price fluctuation	74	21	15	4	1	1	0.256	1
Lack of transport	8	22	20	23	13	6	0.139	3
Limited <i>kocho</i> market information	3	25	26	25	16	12	0.156	2
Far distance of the central market	3	8	5	7	19	21	0.054	7
Poor <i>kocho</i> market policies	18	7	12	10	24	23	0.120	5
Poor linkage with market chain actors	0	7	11	17	7	4	0.060	6
Lack of storage facilities	14	28	21	19	11	7	0.161	4
Low demand for <i>kocho</i>	0	4	9	16	8	12	0.054	7

4. Conclusions and Recommendations

Enset one of the indigenous root crops widely cultivated in the south and southwestern parts of Ethiopia. Its product specifically *kocho* has a significant contribution to the livelihood of producers as source of food and income as well as ensuring of food security in Wonchi district. However, the marketing system of this product is not well documented in the district. To meet the objectives of the study primary data were collected from randomly selected 184 *enset* producer's households in the five kebele in 2018/2019 cropping season and from a total of 33 *kocho* traders using pre tested semi-structured questionnaire.

Five actors have been identified from the survey result as actors of *kocho* market chain in Wonchi district. These actors were producers, wholesalers, retailers, village collectors and consumers. Accordingly, six *kocho* marketing channels were identified through which *kocho* reaches final consumer during its flows from the producer. From the total volume of *kocho* sold by sample producers the largest amount has passed through channel V followed by channel VI). In contrast, the least volume of *kocho* transaction passes through channel II. Total gross marketing margin (TGMM) was highest in channel III and IV (34.99%) and lowest in channel V (11.55%). Survey result showed that, the lack of *enset* seed variety, *enset* disease, weak governmental support, low price and price fluctuation of *kocho*, lack of transport, limited access to *kocho* market information, far distance of the central market from producers location, poor *kocho* market policies, lack of storage facilities and low demand of *kocho* were among major problems of *enset* production and marketing in the study area.

The food security sustaining capacity of the crop at family level and guaranty household food shortage protecting capacity of the crop is more than any other crop type in the community. Therefore, government and any responsible body should give attention for the crop just like other annual crops. Still producers in the study district used *enset* local variety, WDANRO and concerned bodies should be adopting new *enset* variety through partnership with agricultural research center and higher education institutions who works with *enset*. Responsible bodies should pay an attention in optimizing the benefit share and minimizing unbalanced share of benefit among the market actors.

Acknowledgements

We express our sincere gratitude to Oromia Agricultural Research Institute for providing financial support to conduct this research work. We also extend our profound appreciation to all the sample households, the enumerators for their patience throughout the data collection process and provide all the necessary and relevant information, with and without recorded document.
